Delivering Point-of-Care ultrasound teaching using a video conferencing technique

Enseignement de l’échographie au chevet à l’aide d’une technique de visioconférence

Evan Tang, Ryan Daniel, Lauren Wintraub, Matthew W Nelms, Claire Heslop, Dennis Dane Cho and Mirek Otremba

Article abstract

Implication Statement
Point-of-care ultrasound (POCUS) has usually been taught using a hands-on, in-person approach. We present a novel approach to delivering POCUS virtually using a dual image videoconferencing technique. We outline an easily implementable approach and summarize medical students’ experience and feedback. This form of delivery has potential to improve instructional delivery in resource restricted settings or during pandemic restrictions where a hands-on approach may not be possible.

Implication Statement
Point-of-care ultrasound (POCUS) has usually been taught using a hands-on, in-person approach. We present a novel approach to delivering POCUS virtually using a dual image videoconferencing technique. We outline an easily implementable approach and summarize medical students’ experience and feedback. This form of delivery has potential to improve instructional delivery in resource restricted settings or during pandemic restrictions where a hands-on approach may not be possible.

Introduction
Point-of-care ultrasound (POCUS) is becoming a mainstay in healthcare a with a growing number of applications. Both medical knowledge and psychomotor skills for image acquisition are needed. POCUS has usually been taught through a combination of lectures and hands-on learning. The hands-on component allows trainees to develop the psychomotor skills necessary for image acquisition. However, it is unclear whether the hands-on component can be taught successfully without in-person guidance.1 Due to infection concerns, hands-on learning had not been possible during the COVID-19 pandemic. In-person lectures, web-based lectures, and self-directed learning from asynchronous educational videos are alternative modalities being used to teach POCUS but have been unable to completely replicate the hands-on experience.2,3

Telesimulation has been used to provide procedural training in areas such as laparoscopic training, interosseus needle insertion, and ultrasound-guided regional anesthesia.4 However, its utility in providing ultrasound training for novice learners has not been explored. We describe an approach to delivering virtual POCUS teaching to novice learners which fills the gap between lectures and hands-on learning to improve the psychomotor image acquisition skills where in-person sessions are not feasible.

Approach to delivery of ultrasound scanning session
A dual-view approach was implemented, where participants simultaneously observe the placement of the ultrasound probe from a first person-view and the ultrasound image output (Figure 1). We are happy to share
how we were able to achieve this. The session begins with an overview of ultrasound fundamentals, including the technology. The instructor provides an overview of relevant anatomy using the ultrasound while interacting with participants by responding to inquiries in real-time. This is followed by a narrative demonstration of the scan, with a discussion on how to optimize the view and how different movements of the ultrasound probe reflect changes in the acquired image. This approach aims to replicate what students would observe while completing in-person workshops. The ability to simultaneously demonstrate ultrasound probe positioning and the acquired image using virtual livestream technology is a novel educational approach.

Outcomes

We piloted this pedagogy with a group of 10 student volunteers and collected anonymous post-session evaluation (Appendix A). Six (60%) of the participants responded, with all respondents strongly agreeing or agreeing that their knowledge improved and that they felt engaged. Half of the respondents agreed that this approach allowed visualization of the technique with the other respondents reported being neutral (n = 2) or disagreeing (n = 1). Results were presented to faculty and thus garnered support for a broader implementation to the curriculum.

Our faculty scheduled within the curriculum a session on ultrasound basics, focused on assessment with sonography in trauma, and abdominal aorta ultrasound for a class of 134 medical students. No substantial pedagogical changes were made based on the feedback from the pilot session. Twenty-three (17%) students completed the post-session survey. All students (n = 23) strongly agreed or agreed that the objectives of the session were achieved (Appendix B). In addition, 87% (n = 20) of respondents strongly agreed or agreed that this approach allowed visualization of the ultrasound maneuvers.

REB approval was waived by the University of Toronto REB as this was a quality improvement initiative.

Discussion and next steps

This initiative demonstrates the feasibility of a videoconferencing-based approach to teaching early POCUS skills for novice ultrasound users. This has potential application for virtual learning, whether it be for undergraduate medical education or for training practitioners in rural and resource restricted settings, where access to in-person training is a barrier. The dual-video livestream provides learners with real time visualization of image acquisition and ultrasound output, possibly augmenting the development of the necessary psychomotor skills. The results of this work are limited by the single cohort nature of this data in a quality improvement context and continued study is needed.

Next steps will include controlled studies between traditional in-person instruction and this novel pedagogy using objective, competency-based endpoints.

Conflicts of Interest: None Declared
Funding: This initiative received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

Appendix B. Session outline and objectives

Learning objectives:
- Describe the role of POCUS to augment physical examination when looking for free fluid in the chest and abdomen
- Recognize the ultrasound appearance of a pleural effusion and free intra-abdominal fluid

Topics covered:
1. General principles of POCUS
   a. Optimization of images (depth/gain)
   b. Probe selection
   c. Standard imaging convention including probe indicator direction and various planes that are used in ultrasound imaging
   d. Use of color doppler in assessment of vascular structures
2. Abdomen/FAST protocol (Focused Assessment with Sonography for Trauma)
   i. Probe selection
   ii. Demonstration of search for free fluid using the FAST technique
      1. RUQ – Hepatorenal
         a. Understanding Anatomy
            i. Diaphragm
            ii. Liver
            iii. Kidney
            iv. Hepatorenal recess (Morrison’s pouch)
            v. Spine
      2. LUQ – Splenorenal
         a. Understanding Anatomy
            i. Diaphragm
            ii. Spleen
            iii. Kidney
            iv. Hepatorenal recess
            v. Spine
      3. Cardiac – Subxiphoid
         a. Understanding Anatomy
            i. Liver
            ii. Pericardium
            iii. LV/RV
5. Suprapubic
   a. Understanding Anatomy
      i. Bladder
      ii. Uterus/Prostate
3. Aorta
   a. Visualize the abdominal aorta in transverse and longitudinal views
   b. Scan the length of the aorta from upper abdomen to iliac bifurcation
   c. Measure the aorta (transverse & AP diameters). Understand the measurements for normal and abnormal aorta diameters (i.e. AAA)
   d. Understanding of abdominal anatomy to aid in physical examination of the aorta
      i. Relationship to
         1. Liver
         2. IVC
         3. Spine
