Policy and Regulations for New Organisms Supporting Sustainable Pest Management in the United States

Phil Hutton

*Chief, Microbial Pesticides Branch, Biopesticide and Pollution Prevention Division,
Office of Pesticide Programs, United States Environmental Protection Agency,
Washington DC, USA*

BACKGROUND

In the United States, three Agencies are involved with the introduction of new organisms into the environment.

1. U.S. Department of Agriculture, Animal and Plant Health Inspection Service (APHIS)

APHIS guards U.S. borders against foreign agricultural pests and diseases, along with searching for and monitoring agricultural diseases and pests. Therefore, for many organisms, an APHIS permit is required for import of the organism into the United States, or for interstate movement of these organisms. APHIS also issues biotechnology permits for recombinant plants either moved into the United States or between states.

2. Food and Drug Administration (FDA)

FDA is responsible for the safety of food and feed. FDA is also responsible for the enforcement of pesticide tolerances in food and feed. FDA monitors food and feed and does market basket analysis of pesticide residues.

3. Environmental Protection Agency (EPA)

EPA is responsible for the regulation of pesticides in the United States. Therefore, any living organism used to control, repel, or mitigate a pest is regulated by EPA. EPA may register such organisms or exempt them from

registration or regulation. Living organisms that are pesticides are generally categorized as microbial pesticides or plant pesticides. Microbial pesticides include any virus, bacteria, fungi, protozoa, alga, or other microorganism used for pest control.

In certain cases, a microbe may be killed prior to use. If the killed microbe is used in its' entirety, EPA regulates the killed microbe on a case-by-case basis depending upon the cell components that result in its' biological activity. If those components are concentrated, then EPA generally regulates that product as a traditional chemical pesticide. Plant-pesticides include the pesticidal substance and the genetic material necessary for its production in a living plant. Macro-organisms (such as predaceous arthropods) and nematodes already regulated by USDA/APHIS have been exempted from EPA regulation. EPA regulates microbial pesticides and plant pesticides under several federal statutes:

1. Federal Insecticide, Fungicide and Rodenticide Act

This act provides for the registration and regulation of pesticides within the United States. It also allows for the issuance of experimental use permits, emergency exemptions, and certain kinds of state registrations.

2. Food, Drug and Cosmetic Act, and the Food Quality Protection Act

These acts provide for the establishment of tolerances or exemptions from the requirement of a tolerance for levels of pesticides in food or feed.

3. Endangered Species Act

Provides for the protection of certain specified endangered species in the United States.

EXPERIENCE, REGULATORY APPROACH

Experience

So far, EPA has registered 52 viable and 5 non-viable microbial pesticides (table 1.) and 7 plant pesticides (table 2.). The first of these was registered in 1948, but the vast majority of these have been registered in the last 10 years. Applications for the registration of microbial pesticides increased sharply after the

publication of specific guidelines for the registration of these pests in 1984, and again after their revision in 1988. Additionally, the EPA's stated policy of promoting the registration and use of safer pesticides by expediting the review of such sustainable products gave further stimulation to the industry. In general living organisms as pesticides have been less insulting to man or the environment than their traditional chemical counterparts. This is due in large part to the specificity of these products as compared to broad spectrum chemicals. At the present, review of a complete dossier for a new microbial pesticide takes around 12 months, as compared to 3 years for a conventional chemical pesticide. As of this writing, EPA has 11 pending applications for living microbial pesticides and 2 pending applications for plant-pesticides.

B.t. CryIA(b) delta-endotoxin and the genetic material necessary for its production in corn

B.t. CryIA(c) delta-endotoxin and the genetic material necessary for its production in cotton

CryIA(B) delta-endotoxin and the genetic material necessary for its production in corn

Bt. K delta-endotoxin and the genetic material necessary for its production in corn produced by HD-1 gene from plasmid vector pZ01502

Bt. K Cry IA(c) delta-endotoxin and the genetic material necessary for its production in corn

Bt. Tolworthi. Cry 9C delta-endotoxin and the genetic material necessary for its production in corn

Regulatory Approach

In general, the EPA approach to the registration of microbial and plant pesticides is quite different from that for conventional chemicals. Data require-

ments for microbial pesticides revolve around a tiered approach of toxicity and pathogenicity testing using high doses at the initial tier. In addition to characterization and product identity data, as-

assessments are made of potential toxicity and pathogenicity to humans and selected non-target organisms, including avian, fish, aquatic invertebrates, pollinators and plants. Usually, the applicant submits a thorough literature search along with the submitted data.

Product performance (efficacy) data are generally not required unless the proposed use involves public health pests such as mosquitoes, cockroaches, or aflatoxin-producing fungi. Applicants are responsible for the submission of all data, although waivers of some data requirements may be granted if based upon reasonable scientific information. For this reason, most applications contain a thorough literature search of the known data on a specific organism. EPA does have a laboratory audit program through the Office of Compliance and Enforcement which inspects laboratories to ensure the integrity of the data submitted to the Agency. Specific information on EPA data requirements and microbial testing guidelines (series 885) are available from the EPA web site at

http://www.epa.gov/docs/OPPTS_Harmonized/885_Microbial_Pesticide_Test_Guidelines/

Formal established data requirements for plant pesticides in the United States have not as yet been established. However, the following items have been addressed for all of the existing registrations involving proteins from *Bacillus thuringiensis*:

- Product Identity- construct, characterization, markers, vectors
- Protein Digestibility
- Potential Allergenicity
- Expression
- Fate
- Potential gene transfer
- Toxicology
- Non-target Organisms
- Resistance Management

KEY ISSUES

Microbial Pesticides

There are several difficult issues surrounding the registration of microbial pesticides in the U.S. One vexing problem involves the potential toxicity of metabolites from living organisms. In the United States, EPA may ask for specific studies on such metabolites, or require data to quantify the amount of certain metabolites produced by an organism. In some cases, the potential metabolites are well known. However, in other cases, the metabolites may not be known, or if they have been identified then little is known of their respective toxicological profile. Additionally, microbes may produce different metabolites (or different levels of a metabolite) depending upon the substrates available for its growth. This may be true either in production, or after release into the environment. EPA presently responds to these issues on a case-by-case basis rather than through a more consistent data requirement and guideline approach. This has been a most difficult issue for microbial pesticides which are fungi.

A second problem involves the question of how to evaluate the potential for adverse effects to immuno-compromised or otherwise debilitated individuals. This has been the case with a particular bacteria, *Burkholderia cepacia*. *B. cepacia* was registered several years ago, with a complete set of data requirements. However, EPA has recently learned about infections from *B. cepacia* occurring in patients with the disease cystic fibrosis. At this time, we have been unable to determine what testing would be appropriate to separate the clinical strains of this organism from those which would not be opportunistic pathogens. This has, in effect, prevented any further development or testing of the organism, even though some of the strains could be quite beneficial in biological control.
