Résumé de l'article

Bien que la négociation collective soit l'instrument principal de réglementation des salaires, de l'emploi et de l'ensemble des conditions de travail au Canada, il existe beaucoup de confusion quant au nombre exact de syndiqués et de travailleurs régis par les conventions collectives. La mesure la plus utilisée pour calculer ce nombre est le pourcentage de la main-d'œuvre totale non agricole syndiquée; c'est ce qu'on appelle en général la densité syndicale. Cependant, les statistiques relatives à la densité syndicale, bien qu'elles soient appropriées pour jauger l'ampleur du degré potentiel de syndicalisation, sous-estime l'impact véritable de l'activité syndicale, puisque les lois canadiennes en matière de relations du travail exigent que, une fois un syndicat accrédité aux fins de négociations collectives, la convention conclue s'applique à tous les travailleurs compris dans l'unité de négociation, qu'ils soient syndiqués ou pas.

Par conséquent, la proportion des salariés régis par les conventions collectives est plus élevée que celle des syndiqués eux-mêmes. L'écart précis entre les deux groupes a donné lieu à bien des discussions faute de posséder les données requises. Même si on possède une estimation cohérente des effectifs syndicaux publiés par Travail Canada et Statistique Canada, il y a eu, jusqu'à une date récente, une insuffisance déplorable de statistiques dignes de foi touchant le nombre de travailleurs assujettis aux conventions collectives. Les évaluations disponibles varient considérablement, et l'on ne trouve aucune donnée provenant d'une source unique qui compare le nombre de syndiqués à celui des travailleurs régis par les conventions collectives.

Cet article s'efforce de mettre en parallèle le nombre des syndiqués et celui des travailleurs assujettis aux conventions collectives tels que publiés par Travail Canada et Statistique Canada. L'auteur y expose aussi le nouveau mode de calculs tiré d'une étude complémentaire récente de l'Enquête sur la population active au Canada, soit une enquête sur l'adhésion syndicale (EAS) datant de décembre 1984. Il soutient que les nouveaux calculs sont complets et qu'ils sont supérieurs aux statistiques publiées dans le Répertoire des organisations de travailleurs au Canada de Travail Canada, dans CALURA (Loi sur les déclarations des corporations et des syndicats ouvriers) et dans l'enquête de Travail Canada sur les salaires et les conditions de travail. L'EAS fournit pour la première fois des données relatives aux effectifs syndicaux comparativement au nombre des salariés liés par les conventions collectives provenant d'une source unique, ce qui est de nature à favoriser une évaluation plus précise de la densité syndicale et de l'assujettissement des travailleurs aux conventions collectives tout en mettant cette évaluation en regard de celle qui existe aux États-Unis. Elle contient aussi des renseignements de taille par industrie, métier, âge, sexe, scolarité et province qui sont également valables en ce qui a trait à l'influence du syndicalisme dans l'activité économique et à la prévision des secteurs potentiels d'activité syndicale dans l'avenir. La comparaison des estimations pour l'année 1984 à partir de d'autres sources relatives à l'économie globale, par sexe, province et industrie révèle que, si les statistiques traitent des effectifs syndicaux et de la densité syndicale tirées de la nouvelle enquête de Statistique Canada, de CALURA et des enquêtes de Travail Canada sont à peu près comparables, on note une différence marquée entre l'appréciation de l'EAS et celle de Travail Canada pour ce qui a trait aux salariés liés par des conventions collectives. L'évaluation de l'EAS des effectifs syndicaux est presque 11 pour cent plus élevée que celle obtenue par CALURA et à peine 5 pour cent plus haute que l'estimation de l'enquête de Travail Canada sur les organisations de travailleurs.

Toutefois, l'évaluation de Travail Canada du nombre des salariés assujettis aux conventions collectives (58 %) est presque 11 pour cent plus élevée que celle observée dans la nouvelle enquête (46.5 %). L'EAS indique aussi que le pourcentage des travailleurs régis par les conventions collectives en 1984 n'était que 5 pour cent supérieurs à celui des travailleurs syndiqués comparativement au pourcentage de 18 pour cent que présentaient les calculs de Travail Canada.

Estimates of Unionism and Collective Bargaining Coverage in Canada

Pradeep Kumar

This paper presents new estimates of unionization and collective bargaining coverage for Canada from a special Statistics Canada household survey conducted in December 1984. The new estimates are compared with the old estimates.

Although collective bargaining is the major vehicle for regulating pay, employment and working conditions in Canada, considerable confusion exists over its precise scope and coverage. The most common measure of the extent of collective bargaining coverage is the proportion of the non-agricultural workforce that is unionized, generally referred to as union density. However, the union density figures, while appropriate for measuring the extent of potential union organization, understate the true impact of union activity since Canadian labour relations statutes require that once a union is certified for purposes of collective bargaining the resulting collective agreement must cover all employees in the bargaining unit whether union members or not. Thus the proportion of employees covered by collective agreements is generally higher than the proportion who are union members. The precise gap between the two measures, however, has been a source of debate due to lack of appropriate data. While there are fairly consistent estimates of union membership produced by Labour Canada and Statistics Canada, there has been, until recently, an unfortunate lack of reliable data on collective bargaining coverage. Available estimates vary considerably, as noted by Adams (1984) and Riddell (1986), and there have been no comparable statistics on union membership and workers covered by collective agreements from a single source.

This paper presents new estimates of unionism and collective bargaining coverage for 1984 from a recent Statistics Canada supplementary labour

* KUMAR, P., Professor, School of Industrial Relations, Queen's University, Kingston, Ontario.

** The author would like to thank David Arrowsmith for his valuable research assistance, and Scott Murray, Special Surveys Group, Statistics Canada, for providing unpublished tabulations and insightful comments on an earlier draft of the paper.

force survey. The survey collected information on workers who were members of a union as well as those who were not union members but whose wages were covered by a collective agreement negotiated by a union, and provided comprehensive statistics on unionism and the extent of collective bargaining coverage by industry, occupation, age, sex, schooling, etc., not hitherto available. This paper presents these figures and compares them, wherever possible, with estimates from other sources in Canada and with similar estimates in the United States.

SOURCES OF OLD AND NEW ESTIMATES

Union membership and collective bargaining coverage information in Canada is available from three basic sources: union surveys, establishment surveys and household surveys. Each of the three sources provides conceptually different data and has several advantages and disadvantages. Union surveys generally provide only union membership data. Establishment surveys only collect information on collective agreement coverage. The household surveys provide data on both union membership and collective bargaining coverage. Each of the three sources is different in conceptual framework and methodology.

Union Surveys

There are two surveys of union membership in Canada conducted annually, one by Statistics Canada under the *Corporations and Labour Unions Returns Act* (CALURA), and the other by Labour Canada. The CALURA, enacted by Parliament in 1962 and amended in 1981, applies to «every international and national labour union having 100 or more members resident in Canada which has a local union or branch in Canada or that is carrying on activities in Canada independently of any other labour union» (Statistics Canada, 1987, Foreword). Unions are required under the Act to report information in two parts. In the first part, Schedule V of the annual return, unions have to report the number of their locals with membership by sex for each local, affiliation with central federations, names of officers and employees with title, position and the manner of their election or appointment, trusteeship, number of collective agreements of each local with names and industry of employers and the total number of employees and union members covered by each collective agreement as well as detailed information on union policies and practices, qualifications for and restrictions on membership, composition and powers of union ex-

ecutive boards, basic rules of government and other characteristics. The second part, Schedule VI of the annual return, is «privileged» and collects information on financial structure of the unions including extensive data on the costs to Canadian workers of union membership such as total salaries of officers and employees, welfare and pension contributions and benefits payments, strike funds and other union reserve funds.

Information from Schedule V and aggregate data from Schedule VI are published by Statistics Canada in the *Annual Report* under CALURA, usually with a two year lag. The *Annual Report* includes detailed tables and summary analysis of number of unions and their locals and union membership by type of union, affiliation, province, metropolitan area, and by gender. Also included is information on trusteeships with reasons, number of collective agreements by type of union, percent of workers who are union members and distribution of locals and membership of reporting organizations by industry group, and statements of incomes and expenditures of international and national unions and government employees' organizations. The Supplement to the Annual Report lists all reporting organizations with the names of their principal officers, total membership, number of locals, women members, number of collective agreements, amount of per capital dues, etc. by province and metropolitan area.

Although a comprehensive source of union information, the CALURA Report has serious deficiencies. First, it does not cover unions with less than 100 members. Second, because of the lack of specific criteria many independent associations performing union functions are not fully covered. With the amended legislation in 1981 the coverage has become almost complete for teachers' and nurses' associations but a large number of professional associations (police, firefighters, interns and residents, etc.) are still under-represented. Finally, although the number of collective agreements are reported, employees and union members covered by collective agreements are not published due to serious response problems.

The Labour Canada survey, conducted annually, is more complete despite the voluntary nature of the survey vehicle. The survey covers all international and national unions and independent local organizations with 50 or more members. The criteria used are: i) affiliation with a central federation, and/or ii) certification as a bargaining agent by a labour relations board. Consequently, many associations (e.g. police, teachers, nurses and university faculty) excluded under CALURA are more fully covered by the Labour Canada survey. Table 1 compares membership of unions included under CALURA and the Labour Canada survey for the year 1984 (the CALURA figures are as of December 31, 1984 while Labour Canada estimates are for January 1, 1985). The figures indicate that Labour Canada estimates are consistently higher than the CALURA estimates reflecting the larger coverage of the Labour Canada survey.

IWWA	51.2	(44.07)
Membership of unions ¹ listed in CALURA but not in Labour Canada Survey (in '000)	-	6.52
Membership of national and international unions ² listed in Labour Canada Survey but not in CALURA survey (in '000)	59.81	-

1. Unions listed in CALURA survey but not found in Labour Canada's Directory of Labour Organizations, 1985, are: Brewers, Winery and Distillery Workers Union, Local 300; Québec Federation of Forestry Workers; Association of General Practitioners of Laval; Home Care Employees Association; Interior Brewery Workers, Local 308; and Canadian Union of Restaurant and Related Employees.

2. There are as many as 37 national and international unions listed in the Directory of Labour Organizations but not covered by the CALURA survey. Their membership ranges between 53 and 10,000. Included among these are such large unions as Nurses Union of Newfoundland (3,090 members), Ontario Professional Firefighters Association (4,500 members), Québec Provincial Police Association (4,413 members), Seafarers' International Union of Canada (3,064 members), Maritime Fishermans Union (3,000) and the National Brotherhood of Carpenters, Joiners, Foresters and Industrial Workers (Fraternité nationale des charpentiers-menuisiers, forestiers et travailleurs d'usine) with a membership of 10,000 in 1984.

Labour Canada survey estimates are published in the annual *Directory of Labour Organizations in Canada* which contains a summary; statistical data on union membership by congress affiliation, type of union, and by size; and an alphabetical list of all international and national unions, independent local organizations with 50 or more members, central labour congresses, and other labour organizations. There are two major limitations of the Labour Canada survey information. First, small independent local organizations with 50 or fewer members are not covered. Second, the information is not broken down by sex, industry, province, etc. to permit computation of union density rates (such classifications were published until 1977 through a special survey).

Establishment Surveys

Establishment surveys are the principal source of information on collective bargaining coverage. Labour Canada's annual survey of *Wages and Working Conditions in Canada* is the oldest and most comprehensive establishment survey: since 1957 it has provided data on percent of employees covered by collective agreements by occupational group (office, non-office and others), province and industry together with extensive information on wage rates and hours of work by union status for a number of office, service and maintenance occupations (unionized establishments are defined as those where 50 percent or more employees are covered by a collective agreement)¹. The survey estimates are seriously biased upwards and therefore, have been a source of confusion and controversy on the precise difference between union density and collective agreement coverage². For example the overall estimate of collective bargaining coverage in October 1984 was 58 percent based on the Labour Canada establishment survey. The union density, the proportion of non-agricultural paid workers who were union members in January 1985, was only 39.0 percent. The 19 percentage point gap between the degree of unionization and collective bargaining coverage appears too large and difficult to explain on institutional grounds, especially in light of the convincing evidence that «eighty-five percent of employees covered by some form of dues check-off scheme are union members» (Adams, 1984, p. 660).

¹ The annual survey of wages and working conditions in Canada was discontinued by Labour Canada in 1986. The last survey was conducted in October 1985.

² See for example ADAMS (1984) and RIDDELL (1986). Riddell study, prepared for the Royal Commission on the Economic Union and Development Prospects for Canada (commonly referred to as the Macdonald Commission) commented that «Data on both collective bargaining coverage and union membership have important flaws» (fn. 2, p. 83).

The over-estimate of collective bargaining coverage can be attributed to the sample and response bias of the Labour Canada survey. The survey universe in October 1984 consisted of 31,900 establishments employing 20 or more workers with an estimated workforce of 5.5 million, just over one-half of the total non-agricultural paid employees reported by Statistics Canada's labour force survey. Construction industry, agricultural and fishing industries, and educational institutions were excluded. The total survey response was only 53.3 percent and the response rate varied markedly by industry and size of establishment (Labour Canada, 1985, Appendix D). It was significantly higher for highly unionized industries such as public administration (88.0 percent) and for establishments employing 1,500 or more workers (92.0) than for less unionized sectors like trade (47.8 percent) and services (49.4 percent) and for establishments with less than 100 employees (61.1 percent). The large establishment and highly unionized industry sample response bias, together with the unrepresentative nature of the survey, appears to be the main reason for the over-estimate of overall collective bargaining coverage figures derived from the Labour Canada survey. This finding is also confirmed by a comparison of Labour Canada estimates with the estimates of other establishment surveys which have occasionally collected information on collective agreement coverage. For example, a Statistics Canada survey of employee compensation in Canada for the year 1978 found that 46.8 percent of the employees (37.4 percent of the salaried employees and 61.9 percent of the hourly rated wage earners) in Canada were covered by collective agreements (Statistics Canada, 1981, pp. 98-99) compared with the Labour Canada estimate of 58 percent for that year (38 percent for office workers and 72 percent for non-office employees). The Statistics Canada survey, like the Labour Canada survey, covered establishments with 20 or more employees, used the same criteria for collective bargaining coverage, i.e. establishments where one or more employees were covered by a collective agreement, and excluded agriculture, fishing and trapping industries³. However, unlike the Labour Canada survey, the Statistics Canada survey used a representative stratified sample, had a 90 percent response rate, and kept non-sampling errors to a minimum by «the use of a carefully designed and worded questionnaire, a systematic follow up of non respondents and a thorough edit of data and a

³ Employers with 100 or more workers provided separate data for salaried employees and wage earners. All hospitals and employers with less than 100 employees provided data for all employees as a single group. Salaried employees in the Survey included executives, managers, professionals including teachers and academic staff, and technical, clerical and supervisory employees above the level of working foreman. Wage-earners included working foremen, production workers, retail sales clerks, drivers, shipping, warehousing, delivery, maintenance and construction workers. Except for some minor differences these definitions are similar to those used in Labour Canada Survey of wages and working conditions.

rigid control of processing operations» (Statistics Canada, 1981, pp. 31-39). The Construction industry and educational institutions were covered in the Statistics Canada survey but excluded in the Labour Canada survey. The survey revealed that the extent of collective bargaining coverage varied markedly by size of establishment, from 23.5 percent for establishments with less than 100 employees to 66.1 percent for establishments with over 500 workers (Statistics Canada, 1981, Text Table XI, p. 28).

Household Surveys

The use of household surveys for generating union membership and collective bargaining coverage data is a relatively recent phenomenon in Canada. The first attempt was the Survey of 1981 Work History (SWH) conducted by Statistics Canada as a supplement to its monthly Labour Force Survey (LFS) in January 1982. The questionnaire included among others a question on union membership, and was administered to two-thirds of the regular LFS sample. SWH was, however, a complex survey (Statistics Canada, November 1983, pp. 110-119). First, the survey only referred to respondents who worked at some time in 1981, the survey's reference year. Second, the survey collected information on each job held by a respondent over the course of the reference year with up to four different employers. «The design of the questionnaire was such that a particular respondent could have reported employment in up to four different industry groups and four different occupation groups. Depending on the class of worker, there may have been work schedule, union membership and earnings data for any or all of these ... For example, if a person held two paid jobs in 1981, one of which was unionized and the other non-unionized it was difficult to classify the union status of the person» (Statistics Canada, November 1983, p. 111). To alleviate these problems, Statistic Canada created a SWH file in which each paid job was treated as a distinct and independent unit of analysis, as distinguished from more conventional measures of employment. Finally, the survey did not distinguish between union members and those not union members but covered by a collective agreement. The survey simply asked the respondent if he/she «was a member of a union or other group which bargains collectively with this employer?» Thus the survey provided information only on paid jobs in 1981 which were either unionized or non-unionized rather than on the union status of the workers. The survey estimates revealed that 31.2 percent of the

«paid jobs» in 1981 were unionized,⁴ a considerably lower estimate than the 39.0 percent figure for union membership as a percentage of non-agricultural paid workers reported by Labour Canada's union survey in January 1982.

A more refined household survey, the Survey of Union Membership (SUM), was conducted by Statistics Canada in December 1984, again as a supplement to the Labour Force Survey, whose main purpose was «to address issues related to union membership and collective bargaining» (Statistics Canada, December 1985, p. 146)⁵. The survey covered approximately 46,000 households or 100,000 individuals, five-sixths of the LFS sample. The survey asked respondents, who were either employed in December 1984 as a paid worker or if not employed and laid off in the reference week but whose most recent job in 1984 was a paid job, whether (1) he/she was a member of a union or other group which bargained collectively with an employer, and (2) although not a member of a union were his/her wages covered by a collective agreement negotiated by a union or other group? Respondents were also asked to report their usual wage or salary before deductions. The objective of the question was to collect data on employment income which could be used in conjunction with other information to derive an hourly earnings or wage rate. The SUM was able to generate valuable data on union membership, collective bargaining coverage of union and non-union workers as well as extensive information on union and non-union wage rates for a variety of demographic and labour market groups. Moreover, as the SUM questions on union membership and collective bargaining coverage were identical to the questions asked in the

4 The survey showed that the incidence of unionization was considerably higher among men (35.9 percent) than women (25.0 percent), in full time jobs (35.2 percent) compared to part-time jobs (15.0 percent). The Survey found little difference between the sexes in the proportion of part-time jobs that were unionized. However 38.9 percent of full time jobs held by men were unionized compared to 29.2 percent for women. Another interesting finding of the Survey was that women in unionized jobs were typically more educated than men. A sizable minority of women in unionized jobs (42.2 percent of the total) were those in managerial and professional occupations. The proportion of unionized men in these occupation as a comparison was less than (17.7 percent) half that of women (for details see Statistics Canada, November 1983, pp. 83-119).

5 The Survey of union membership was jointly sponsored by Labour Canada and Statistics Canada, and was designed primarily to provide answers to the following questions: (i) how many paid workers have their wages and other conditions of work determined by a collective agreement; (ii) among those employees who are covered by collective agreements, how many are actually union members; (iii) what are the characteristics of union members, for example which industries and provinces are the most highly unionized; and (iv) do the wages and pension plan coverage of union members and non-union workers differ significantly?

American household survey, the Current Population Survey,⁶ the survey made it possible to compare accurately the extent of union membership in the two countries.

Encouraged by the success of the past two supplementary surveys, the SWH in January 1982 and the SUM in December 1984, Statistics Canada is now conducting a comprehensive Labour Market Activity Survey, one undertaken in January/February 1987 to collect data for the 1986 reference year and a longitudinal follow up survey planned for January 1988 to obtain data for the 1987 reference year⁷. The survey will include among others the two questions asked in the Survey of Union Membership in December 1984 relating to union membership and collective bargaining coverage.

NEW ESTIMATES OF UNION MEMBERSHIP AND COLLECTIVE BARGAINING COVERAGE

The 1984 Survey of Union Membership (SUM) conducted by Statistics Canada disclosed that there were a total of nearly 3.87 million union members in December 1984 of whom 3.47 million were employed and approximately 394,000 were laid off from their most recent paid job. Another 526,000 workers, of whom 430,000 were employed and the remaining 96,000 were on lay-off, reported that while they were not union members their wages were covered by a collective agreement between their employer and a union. Adding the two figures (union membership and non-union

⁶ The Current Population Survey (CPS) is a monthly survey of about 60,000 households in the United States which provides basic information on the nation's labour force, similar to the monthly Labour Force Survey in Canada. Beginning in January 1983, two special questions focusing on union membership and collective bargaining coverage were added to the questionnaire used in the Survey. The Survey questions relating to unions are the last in a sequence focusing on the nature of the job held by employed persons, the hours worked and the hourly and weekly earnings. After providing this information the Survey respondent is asked whether on this job the worker in question «is a member of a labour union or of an employee association». If the answer is «no» a further question is asked whether the worker is «covered by a union or employee association contract» (for details on the concepts and data see *Employee and Earnings*, January 1985, and Larry ADAMS (1985)).

⁷ The Labour Market Activity Survey is being conducted by Statistics Canada with the cooperation and support of Employment and Immigration Canada. The objectives of the Survey are: (a) «to provide dynamic measures of the Canadian labour market over a 24-month period which are conceptually consistent with the Labour Force Survey»; and (b) to provide information on the characteristics of paid jobs held which are not available from the Labour Force Survey (LFS). The Survey, «administered as two separate but identical surveys», is being conducted as a supplement to the January 1987 and the February 1987 cycles of the LFS with a longitudinal follow-up planned for January 1988. Among others, the Survey will provide estimates relating to the characteristics of paid jobs in terms of unionization, usual wage rates and hours, coverage under collective agreements and pension plans.

workers covered by collective agreements) gives an estimate of 4.39 million workers (both employed and those laid-off) who were covered by collective agreements in 1984. Based on these estimates, the difference between union density and collective bargaining coverage in 1984, the two measures of union activity, was around 5 percentage points; average union density was between 34 and 37 percent (37 percent of those employed in December 1984 and 34 percent of all paid workers including both employed and laid-off) whereas the percent of workers covered by collective agreement was between 42 and 39 percent respectively. Tables 2 to 6 present detailed unpublished estimates of unionism and collective bargaining coverage by age, sex, schooling, full-time, part-time status and by industry, occupation and province, based on the 1984 Statistics Canada Survey, SUM. Table 7 compares estimates of unionism and collective bargaining coverage for the United States and Canada for 1984 based on similar household surveys.

The SUM figures show that unionization rates (and collective bargaining coverage) vary markedly by demographic and related labour market status of workers. For example, 42 percent of all males and 32 percent of all females were unionized in 1984. Union membership was significantly higher among full time workers and prime age (35-54 years) men than among part-time worker, and youth; among the highly educated (with post-secondary degree) and workers with less than 8 years of schooling than among workers with secondary education. By *industry*, union organization was at or near saturation (with two-thirds or more workers organized) in public administration, quasi-public education and health sectors, communications and utilities, in such manufacturing industries as paper and transportation equipment, and in non-metal mining. Almost one-half of the workers were unionized in fishing, metal mining, food and beverage, textile, wood products, primary metals, non-metallic mineral products and in transportation. By *occupation*, the proportion of workers unionized was two-thirds or more among teachers, nurses, government administrators, and in most blue-collar processing, machine assembling and trades occupations; and between two-fifths and one-half among professionals in life sciences, social sciences (except in law and jurisprudence), medicine and health, in such clerical occupations as file clerks and receptionists, among protective service and hotel workers, and in most fishing, forestry and mining occupations. By *province*, British Columbia, Québec and Newfoundland had the highest rate of unionization; Alberta was the least unionized, while in other provinces unionization was close to or slightly less than the national average.

A comparison of union density and collective bargaining coverage estimates by gender, age, schooling, industry, occupation and province also revealed that in an overwhelming majority of cases the difference between

the two measures of unionization was less than 10 percent; in only two occupations was collective bargaining coverage between 12 — 14 percentage points higher and in one industry (tobacco) the coverage was nearly 29 percentage points higher than the unionization rate.

1 Union membership as a percent of paid workers.

2 Figures in parentheses exclude unemployed, workers on layoff from their most recent job, pensioners, etc.

Source: For CALURA data: Statistics Canada, Corporations and Labour Unions Returns Act, 1984.

Part II and Statistics Canada, The Labour Force, 71-001, December 1984. Provincial figures include unemployed, pensioners, etc.

For Statistics Canada Survey: unpublished data from the December 1984 supplementary labour force survey on «union membership».

For Labour Canada Survey: unpublished data from the 1984 survey of Wages and Working Conditions in Canada.

A COMPARISON OF ALTERNATE ESTIMATES

Table 8 presents comparable estimates of union membership, union density and collective bargaining coverage for 1984 from alternate sources for the total economy and by gender, province and industry. Figures indicate that while union membership and union density figures from the new Statistics Canada household survey, SUM, and the CALURA and Labour Canada surveys are roughly comparable, there is a great divergence between SUM and Labour Canada estimates of collective bargaining coverage. The overall SUM estimate of union membership is nearly 11 percent higher than the CALURA estimate and only 5 percent more than the estimate derived from the Labour Canada annual survey of labour organizations. The divergence between SUM and the CALURA estimate is only 3 percent when only employed union members are compared. It appears that the discrepancy between the two estimates can be largely attributed to a considerably higher figure of unemployed and laid off union workers in the household survey, and the problems of generating population estimates from a small sample in some provinces and industries⁸. Thus although the CALURA and SUM estimates of union membership for most categories vary between zero and 10 percent, the divergence is significant in estimates of women members (both employed and unemployed) and of union membership in Newfoundland, in agricultural, fishing, mining, construction and finance. A comparison of CALURA and Labour Canada estimates based on the survey of unions also suggests that the CALURA survey generally underestimates union membership because of its exclusion of unions with less than 100 members and incomplete response from professional and related national unions and associations. Union density figures from the CALURA survey and the SUM also diverge on account of problems of small sample for some provinces and industries and the slight difference in

⁸ The coefficient of variation of the estimates, the standard error of the estimate divided by the estimate is inversely related to the size of the estimate. The crude sampling variability tables for aggregate paid worker estimates of the Survey of Union Membership show that the coefficient of variation is less than 16.5 percent for estimates *greater than* 13,000 for Canada; 4,000 for Newfoundland, Prince Edward Island and New Brunswick; 5,500 for Nova Scotia; 20,000 and 24,000 for Québec and Ontario respectively; 7,000 for Manitoba, 5,000 for Saskatchewan, 10,000 for Alberta and 15,500 for British Columbia. Under Statistics Canada Guidelines, the estimates below 4,000 or estimates with a coefficient of variation of over 25 percent are not «reliable» and may not be released. The unweighted univariate counts from the Survey showed that estimates for Prince Edward Island, Newfoundland, for age groups 15-19 and 65-69, for workers with a job tenure of over 20 years, and for a number of two-digit SIC industries and three-digit CCDO occupations were too low to provide very reliable estimates.

estimates of paid workers to calculate the percent of union organization⁹. In general, however the percentage point difference between the two estimates is less than five. The divergence is significantly higher when unemployed and laid off workers are included in total union membership¹⁰. There are also wide variations in estimates for Newfoundland, and for agriculture, fishing, forestry, mining and construction industries.

The new estimates of collective bargaining coverage from the SUM also differ markedly from the Labour Canada estimates based on a survey of establishments. In aggregate, as well as for individual provinces and industries Labour Canada estimates are significantly higher than the SUM estimates. The differences primarily relate to the poor sample design of the Labour Canada survey, in particular the survey sample and response bias towards large establishments and sectors with a high degree of unionization.

CONCLUSION

The new estimates from the recent Statistics Canada's supplementary household survey, the survey of union membership in December 1984, are a welcome addition to the alternate estimates of unionism and collective bargaining coverage. The diverse range of cross-classified information generated from the survey will be extremely useful for both researchers and union organizers. The estimates will hopefully put to rest the controversy over the size of the differential between the percent of workers who are union members and the percent of employees covered by collective agreements. As well the data should be valuable for studies of economic effects of unionism, and help unions assess more effectively the potential areas of future organization.

⁹ The LFS estimate of paid workers for December 1984 used to calculate the union density with CALURA union membership figures, was about 455 thousand more than the paid worker estimate from the SUM. The difference was accounted for by multiple job holders and working owners of incorporated businesses treated as paid workers in the LFS estimates but excluded from the SUM.

¹⁰ The CALURA estimate of unemployed and retired union members in 1984 was 58,862 compared to 394,000 in the SUM.

***Travailleurs syndiqués et travailleurs couverts
par conventions collectives au Canada***

Bien que la négociation collective soit l'instrument principal de réglementation des salaires, de l'emploi et de l'ensemble des conditions de travail au Canada, il existe beaucoup de confusion quant au nombre exact de syndiqués et de travailleurs régis par les conventions collectives. La mesure la plus utilisée pour calculer ce nombre est le pourcentage de la main-d'oeuvre totale non agricole syndiquée; c'est ce qu'on appelle en général la densité syndicale. Cependant, les statistiques relatives à la densité syndicale, bien qu'elles soient appropriées pour jauger l'ampleur du degré potentiel de syndicalisation, sous-estime l'impact véritable de l'activité syndicale, puisque les

lois canadiennes en matière de relations du travail exigent que, une fois un syndicat accrédité aux fins de négociations collectives, la convention conclue s'applique à tous les travailleurs compris dans l'unité de négociation, qu'ils soient syndiqués ou pas. Par conséquent, la proportion des salariés régis par les conventions collectives est plus élevée que celle des syndiqués eux-mêmes. L'écart précis entre les deux groupes a donné lieu à bien des discussions faute de posséder les données requises. Même si on possède une estimation cohérente des effectifs syndicaux publiés par Travail Canada et Statistique Canada, il y a eu, jusqu'à une date récente, une insuffisance déplorable de statistiques dignes de foi touchant le nombre de travailleurs assujettis aux conventions collectives. Les évaluations disponibles varient considérablement, et l'on ne trouve aucune donnée provenant d'une source unique qui compare le nombre de syndiqués à celui des travailleurs régis par les conventions collectives.

Cet article s'efforce de mettre en parallèle le nombre des syndiqués et celui des travailleurs assujettis aux conventions collectives tels que publiés par Travail Canada et Statistique Canada. L'auteur y expose aussi le nouveau mode de calculs tiré d'une étude complémentaire récente de l'Enquête sur la population active au Canada, soit une enquête sur l'adhésion syndicale (EAS) datant de décembre 1984. Il soutient que les nouveaux calculs sont complets et qu'ils sont supérieurs aux statistiques publiées dans le *Répertoire des organisations de travailleurs* au Canada de Travail Canada, dans CALURA (*Loi sur les déclarations des corporations et des syndicats ouvriers*) et dans l'enquête de Travail Canada sur les salaires et les conditions de travail. L'EAS fournit pour la première fois des données relatives aux effectifs syndicaux comparativement au nombre des salariés liés par les conventions collectives provenant d'une source unique, ce qui est de nature à favoriser une évaluation plus précise de la densité syndicale et de l'assujettissement des travailleurs aux conventions collectives tout en mettant cette évaluation en regard de celle qui existe aux États-Unis. Elle contient aussi des renseignements détaillés par industrie, métier, âge, sexe, scolarité et province qui sont également valables en ce qui a trait à l'influence du syndicalisme dans l'activité économique et à la prévision des secteurs potentiels d'activité syndicale dans l'avenir.

La comparaison des estimations pour l'année 1984 à partir de d'autres sources relatives à l'économie globale, par sexe, province et industrie révèle que, si les statistiques traitant des effectifs syndicaux et de la densité syndicale tirées de la nouvelle enquête de Statistique Canada, de CALURA et des enquêtes de Travail Canada sont à peu près comparables, on note une différence marquée entre l'appréciation de l'EAS et celle de Travail Canada pour ce qui a trait aux salariés liés par des conventions collectives. L'évaluation de l'EAS des effectifs syndicaux est presque 11 pour cent plus élevée que celle obtenue par CALURA et à peine 5 pour cent plus haute que l'estimation de l'enquête de Travail Canada sur les organisations de travailleurs. Toutefois, l'évaluation de Travail Canada du nombre des salariés assujettis aux conventions collectives (58%) est presque 11 pour cent plus élevée que celle observée dans la nouvelle enquête (46.5%). L'EAS indique aussi que le pourcentage des travailleurs régis par les conventions collectives en 1984 n'était que 5 pour cent supérieur à celui des travailleurs syndiqués comparativement au pourcentage de 18 pour cent que présentaient les calculs de Travail Canada.
